20. ABSTRACT (Continue on reverse side if necessary and identify by block number)  <p>As a part of the U.S. Armed Forces anthropometric surveys of 1966, a sample of 2008 U.S. Marine Corps men was measured. The sample included 1003 men measured at Camp Lejeune, North Carolina, and 1005 men measured at Camp Pendleton, California. Seventy body measurements were taken on each man. The anthropometric data from this survey are presented and discussed in this report.</p>

## PREFACE

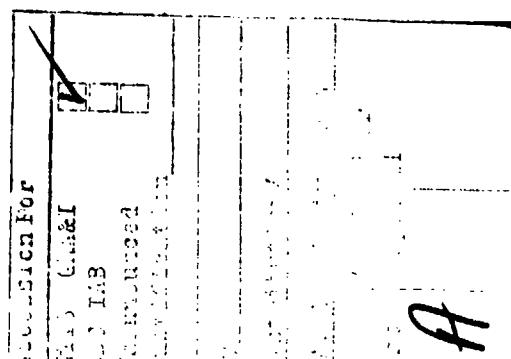

In the research and development of military materiel, the man and his equipment must be considered as an integrated system. A basic requirement in this concept, however, is that adequate information on human body size be provided for use in the design and sizing of equipment and materiel. Data on the variability of body size in the user population must be available to develop a suitable range of sizes in clothing or to provide adequate design and adjustability in equipment. Only in this way can the man and his equipment be successfully integrated to increase compatibility and improve performance.

The fact that large numbers of men are available for measurement presents a unique opportunity for anthropometric research in the "population laboratory" represented by personnel of the U.S. Armed Forces. Anthropometric data on U.S. Army and Air Force personnel have been available and in use for over 30 years. Anthropometric surveys of the U.S. Armed Forces, carried out in 1966, made possible an up-dating of these data and, for the first time, provided standard anthropometric data for all of the services.

The body size characteristics of U.S. Marine Corps men are presented in this report. The anthropometric data on Marines originally were collected in 1966. The processing, reduction, editing, and analyses of the data required several years to accomplish. The preparation and writing of this technical report, together with the compilation of the many tables of anthropometric data, has proved to be a lengthy process, often interrupted by research and other work of higher priority. However in spite of the long delay in publication, it is believed that the anthropometric data presented in this report will be of interest and use in the development and sizing of Marine Corps clothing and equipment.

A large number of people aided in the conduct of the Marine Corps anthropometric survey through their active participation, cooperation, and assistance. Had it not been for the cooperation of the 2000 men who were measured, as well as the assistance of their commanding officers and staffs, there would have been no anthropometric data to report. This report is dedicated with respect and admiration to the men of the United States Marine Corps.

The members of the measuring teams deserve full credit and acknowledgement for their long and tedious hours of measuring during the survey. The following men served on the measuring teams: SFC Emmett Headley, SSG Eli B. Oliver, SSG Theodore Stephens, SGT Howard E. Crockett, SGT Robert J. Hayes, SGT Thomas P. Skizenski, SP5 John D. Petraitis, SP5 Ira W. Clark, CPL Frank A. Mills, CPL Warren E. Stiles, CPL Andrew Taylor, SP4 Bobby L. Adams, SP4 Marvin J. Ingram, SP4 Harold D. Leonard, SP4 Don R. Montgomery, SP4 Robert A. Perrigo, SP4 Wilson E. Taylor, SP4 Otton E. Williammee, Jr., SP4 Frank D. Wood, PFC Daniel J. Arnold, PFC Ronald M. Davison, PFC Harlan G. Garbe, PFC Victor A. Kowalski, PFC Kris K. Snyder, and PFC Charles F. Troxell.

The anthropometric survey of U.S. Marine Corps personnel was carried out in 1966. The active participation in the survey of the former U.S. Army General Equipment Test Activity, then located at Fort Lee, Virginia, and the support of Dr. Howard W. Hembree, then Technical Director, and his staff is acknowledged. This activity provided the organization and personnel to make the survey a success. Major John E. Donaldson admirably performed all of the administrative and planning functions which were necessary to schedule and maintain the measuring team's travel and activities. Able assistance was provided by Staff Sergeant Jackie W. Snyder as administrative coordinator. At various times during the survey, Captain Theodore A. Lide, Second Lieutenant James E. Gardner, and Second Lieutenant Lynn W. Kling, Jr. had the responsibility of leading and supervising the measuring teams; they performed this assignment very competently.

The cooperation and assistance of Mr. Charles E. Clauser and other members of the Anthropology Branch, Aerospace Medical Research Laboratory, Wright-Patterson Air Force Base, Ohio, is gratefully acknowledged with thanks. Through the cooperation of the U.S. Air Force, Mr. Edmund Churchill and the staff of the Anthropology Research Project carried out the exacting task of reducing and processing the data — it is largely their work which is presented in this report. Mr. Churchill also prepared the sections of this report on Data Processing and the Statistical Measures.

During his term as an assistant in the Anthropology Laboratory at Natick, Mr. Richard L. Burse was extremely helpful in planning the survey, in the training program for measurers, and in analyzing the results of the survey.

The illustrative sketches in this report are the work of Mrs. M. J. Kennedy, whose able assistance is acknowledged with thanks.

## **UNITED STATES MARINE CORPS ANTHROPOMETRY**

### **1. INTRODUCTION**

#### **a. Military Anthropometry**

A fundamental concept in the area of military research and development is represented by the so-called "systems approach". According to this concept, the man or the individual soldier together with his equipment, whether it be personal equipment he is wearing or using or a machine he is operating, is considered to be a man/equipment system. A basic requirement for the efficient use and operation of such a system is that the man and the equipment be compatible.

Effective human engineering plays an important role in achieving such compatibility. Since anthropometric data constitute a basic requisite for defining the elements of body size in the human engineering of man/equipment systems, anthropometry provides an essential input in the development of such systems.

Anthropometry is the measurement of the human body. Since effective human engineering requires the use of body size data on the specific population for which the equipment is intended, military anthropometry is one important source of the information necessary for the design and sizing of equipment and materiel to be used by the Armed Forces.

Anthropometric data are collected by measuring large, representative samples of the military population. Through the compilation, processing, analysis, and synthesis of such data, it is possible to provide a metric description of the military population. This information is then available for general use in the design and human engineering of military equipment and materiel, as well as for specific application in the design, sizing, and tariffing of clothing and individual equipment.

Anthropometric surveys have been conducted on all of the United States Armed Forces. To provide wide availability for such information, the anthropometric data obtained during these surveys are published in a series of technical reports. A report on the Army survey has been published. It is the purpose of the present report to present anthropometric data on men of the United States Marine Corps.

#### **b. Historical Summary**

Military anthropometry in the United States is not a new development, since anthropometric data on military personnel have been in use for at least 100 years or more. Some data on the body size of soldiers in the Civil War are available. Large quantities of anthropometric data were collected during and at the end of World War I, and an extensive anthropometric survey was conducted by the U. S. Army in 1946 at

the conclusion of World War II. A brief review of military anthropometry in the United States will indicate the primary sources of anthropometric data prior to the surveys of 1966.

Information on the body size of Civil War soldiers was reported by Gould in 1869<sup>1</sup> and by Baxter in 1875.<sup>2</sup> Although these data include only a few body size measurements, they do provide some indication of the body size of soldiers some 100 years ago.

A large volume of anthropometric data and statistics on World War I soldiers was published by the Medical Department of the U. S. Army, in 1921.<sup>3</sup> In this monumental work, Davenport and Love analyzed data on some 2,000,000 draft recruits of 1917-1918, and on 100,000 troops demobilized in 1919. While a large part of the material in this volume consists of medical or clinical information, it is significant that extensive analyses were made of the correlations between body size and clothing size. In fact, many of the procedures utilized today in applied military anthropometry may be traced to the work of Davenport and Love in 1921.

Interest in the utilization and application of anthropometric data was renewed early in World War II with the establishment of the Anthropology Branch at the Aero Medical Laboratory, Wright Field, Dayton, Ohio, where anthropologists conducted anthropometric studies and carried out human engineering work on aircraft cockpits, gun turrets, oxygen masks, and flight clothing throughout the war. A summary of this work in applied anthropometry by Randall, Damon, Benton and Patt was published in 1946.<sup>4</sup>

<sup>2</sup>Baxter, J. H. Statistics, medical and anthropological, of the Provost Marshal General's Bureau, derived from the records of the examination for military service in the Armies of the United States during the late war of the rebellion, of over a million recruits, drafted men, substitutes and enrolled men. 2 volumes. U. S. Government Printing Office, Washington, D. C., 1975.

<sup>3</sup>Davenport, C. B., and A. G. Love. The Medical Department of the United States Army in the World War, Volume 15, Statistics; Part 1, Army anthropology. U. S. Government Printing Office, Washington, D. C., 1921.

<sup>4</sup>Randall, Francis E., Albert Damon, Robert S. Benton and Donald I. Patt. Human body size in military aircraft and personal equipment. Army Air Forces Technical Report No. 5501, Air Materiel Command, Wright Field, Dayton, Ohio, June 1946. (ATI 25 419)

Following his active duty in the Army Air Forces, Francis E. Randall transferred to the Army Quartermaster Corps, where he planned and carried out the Army anthropometric survey of 1946. This was the first extensive survey to be conducted primarily to provide body size data for military clothing sizing and tariffing; it included the measurement of both men and women. In this survey, 105,062 Army men were measured at six separation centers. Of the total series, 96,381 men were separatees, and 8,681 men were new inductees. Sixty-six body measurements were taken on each individual, while body build photographs were obtained on 49,500 men. In the series of 8,859 Army women measured, 5,116 were Women's Army Corps (WAC) personnel, while 3,742 were Army nurses. The data from these surveys were published in a series of some twelve technical reports between 1947 and 1952. The basic data on women were reported by Randall and Munro in 1949,<sup>5</sup> and the data on men were reported by Newman and White in 1951.<sup>6</sup>

As an outgrowth of the Army's work in anthropometry and clothing, a similar effort was initiated in the United States Marine Corps in 1948. This resulted in a survey of some 2,000 Marine Corps personnel, carried out by William J. Beer, a Marine Corps officer. The anthropometric data collected were used extensively in the development and sizing of Marine Corps clothing and equipment, but unfortunately the data were never published in report form.

Another anthropometric survey was carried out by the Army Quartermaster Corps in 1949, primarily to obtain additional data on Army men in the younger age groups. In this survey, 7,272 men were measured, including draftees, enlistees, and re-enlistees. Although these data have been utilized in research, they have not been published.

With the establishment of the United States Air Force as a separate service, anthropometric surveys of Air Force personnel were carried out in 1950-1952. A series of 4,063 USAF flying personnel were measured at fourteen air bases in 1950; 132 body measurements were taken. This series consisted of 61 percent officers, 15 percent cadets, and 24 percent enlisted men. In 1952, a survey of 3,332 Air Force basic trainees was conducted, in which 60 measurements were taken. Also in 1952, 63 measurements were taken on a series of 852 Women's Air Force (WAF) personnel. The anthropometric data from these three surveys were published in a large number of reports. The basic report

<sup>5</sup> Randall, Francis E., and Ella H. Munro. Reference anthropometry of Army women. Report No. 149, U. S. Army Quartermaster Climatic Research Laboratory, Lawrence, Mass., March 1949. (AD 209 837)

<sup>6</sup> Newman, Russell W., and Robert M. White. Reference anthropometry of Army men. Report No. 180, U. S. Army Quartermaster Climatic Research Laboratory, Lawrence, Mass., September 1951. (AD 149 451)

on USAF flying personnel by Hertzberg, Daniels and Churchill was published in 1954,<sup>7</sup> and has been widely used as a standard reference for anthropometric data. The series of USAF basic trainees was reported by Daniels, Meyers and Churchill in 1953,<sup>8</sup> while the WAF data on women were reported by Daniels, Meyers and Worrall, also in 1953.<sup>9</sup>

To meet an increasing need for specific data on personnel in Army aviation, an anthropometric survey of Army aviators was carried out in 1959. The data, consisting of 41 measurements on 500 Army pilots, were published by White in 1961.<sup>10</sup>

An anthropometric survey of 1,549 Navy and Marine Corps aviators was carried out in 1964, in which 96 measurements were taken. The report by Gifford, Provost and Lazo was published in 1965.<sup>11</sup>

#### c. The U. S. Armed Forces Anthropometric Surveys

New anthropometric surveys of the U. S. Armed Forces were first proposed in April, 1964. The surveys were requested and sponsored by the Defense Supply Agency, with the ultimate objective of achieving improvements in the sizing, fit, tariffing, distribution, and issue of military clothing and personal equipment.

<sup>9</sup> Daniels, Gilbert S., H. C. Meyers, Jr., and Sheryl H. Worrall. Anthropometry of WAF basic trainees. WADC Technical Report 53-12, Aero Medical Laboratory, Wright-Patterson Air Force Base, Ohio, July 1953. (AD 20 542)

<sup>10</sup> White, Robert M. Anthropometry of Army aviators. Technical Report EP-150, U. S. Army Quartermaster Research and Engineering Center, Natick, Mass., June 1961. (AD 263 357)

<sup>11</sup> Gifford, Edmund C., Joseph R. Provost and John Lazo. Anthropometry of Naval aviators—1964. Report NAEC-ACEL-533, Aerospace Crew Equipment Laboratory, U. S. Naval Air Engineering Center, Philadelphia, Pa., October 1965. (AD 626 322)

The purpose of the new surveys was two-fold. Initially, there existed a requirement for the up-dating of anthropometric data on the U. S. military population. Since the basic Army data were some 20 years old and the Air Force data were about 15 years old at the time, new body size information was needed for men in the Armed Forces. Secondly, it was recognized that data should be obtained from all of the Armed Forces, so that the surveys were planned to include samples from the major groups comprising the U. S. military population.

In planning the anthropometric surveys, it was agreed that surveys of Army, Marine Corps, and Navy personnel would be conducted by U. S. Army anthropologists, while those of Air Force personnel would be carried out by Air Force anthropologists. Following a year of planning, preparation and coordination, the surveys were initiated in August, 1965, when the Air Force obtained 158 body measurements on a series of 2,632 USAF basic trainees. Seventy body measurements were taken in the Army, Marine Corps, and Navy surveys, which were carried out between November, 1965 and April, 1966. The total Army series of 6,682 men included 2,639 basic trainees, 3,429 infantry personnel, 489 armored crewmen, and 125 Army aviation personnel. The Marine Corps sample consisted of 2,008 men, of whom 1,003 were measured at Camp Lejeune, North Carolina, and 1,005 men at Camp Pendleton, California. The Navy series comprised 4,095 recruits, half of whom were measured at Great Lakes, Illinois, and half at San Diego, California. The field work of the surveys was completed in 1967, when the Air Force obtained 187 measurements on a series of 2,420 USAF flying personnel between January and March, 1967.

The results and analyses of data from the Army survey were published in an extensive report by White and Churchill in 1970.<sup>12</sup> The data on U. S. Navy recruits have been processed and studied, but have not been published as yet in a technical report.

Subsequent to the Armed Forces surveys, two additional anthropometric surveys of U. S. Army aviation personnel were carried out. In the first, nine body measurements were made on a series of 1,640 Army warrant officer candidate flight trainees in 1968; the report by Schane, Littell and Moultrie was published in 1969.<sup>13</sup> In the second survey,

<sup>12</sup>White, Robert M., and Edmund Churchill. The body size of soldiers: U. S. Army anthropometry—1966. Technical Report 72-51-CE, U. S. Army Natick Laboratories, Natick, Mass., December 1971. (AD 743 465)

<sup>13</sup>Schane, W. P., D. E. Littell and C. G. Moultrie. Selected anthropometric measurements of 1640 U. S. Army warrant officer candidate flight trainees. USAARL Report No. 69-2, U. S. Army Aeromedical Research Laboratory, Fort Rucker, Alabama, February 1969. (AD 688 856)

a series of 1,482 Army aviators were measured in 1970; 85 body measurements were taken. A report on the data by Churchill, McConville, Laubach and White was published in 1971.<sup>14</sup>

An anthropometric survey of U. S. Air Force women was conducted in 1968, in which 137 measurement were made on a sample of 1,905 women, including nurses, officers and enlisted women. The report by Clauser and co-authors was published in 1972.<sup>15</sup> In 1976-1977, an anthropometric survey of U. S. Army women was carried out in which 128 measurements were obtained on 1,330 basic trainees, officers, and nurses. A series of reports by several authors was published in 1977.<sup>16,17,18</sup> In addition, a small series of Army men also were measured at the end of the women's survey; the report by McConville, Churchill, Churchill and White also was published in 1977.<sup>19</sup>

Two annotated bibliographies are available which may be of interest in this review of U. S. military anthropometric surveys. The latest edition of the U. S. Air Force annotated bibliography of applied physical anthropology was prepared by Reid in 1976:<sup>20</sup> it includes summaries of Air Force publications between 1946 and 1976. An annotated bibliography of U. S. Army publications between 1947 and 1976 was prepared by White in 1977.<sup>21</sup> In the area of physical anthropology, this includes summaries of technical reports, articles, and papers on anthropometry, applications, constitutional and environmental anthropology, and human identification.

The anthropometric surveys of the U. S. Armed Forces, carried out between 1965 and 1967, represented a new approach in that for the first time standard body measurements were taken in coordinated surveys on personnel of all the military services within the same time frame. The data provided a basis for describing the body size of the military population of the United States and made possible direct comparisons of body size among personnel of the Armed Forces.

#### d. Summary of Report

The results of an anthropometric survey of the United States Marine Corps are presented in detail in this report.

In Section 2, the Marine Corps survey is discussed in terms of the planning and organization of the survey, the methodology and techniques of measurement used, and the locations and times of the measuring.

The methods of data processing, including data reduction, editing, and the computation of statistics are presented in Section 3.

The sample of Marine Corps men measured in the survey is discussed in Section 4. The background information obtained during the survey serves to describe the characteristics of the men in terms of military information, such as rank and length of military service, and personal information, such as age, birthplace, education, and other items.

<sup>21</sup> White, Robert M. An annotated bibliography of U. S. Army anthropology (1947-1977). Technical Report NATICK/TR-78/012, U. S. Army Natick Research and Development Command, Natick, Mass., December 1977. (AD A060 939)

The statistics used in the presentation of the anthropometric data are explained and discussed in Section 5.

In Section 6, the detailed anthropometric data obtained during the survey are given, together with an index of dimensions, as well as a visual index of the body measurements.

Summary tables of statistical and percentile values for the anthropometric data are presented in Section 7.

An analysis and discussion of the Marine Corps anthropometric data are given in Section 8. Comparisons of the Marine Corps subseries, and comparisons of the Marine Corps data with similar U. S. Army data are included here.

Section 9 contains a summary and conclusions of the survey. A list of references may be found in Section 10. The data sheet used in the survey is reproduced in the Appendix.

## 2. THE U. S. MARINE CORPS ANTHROPOMETRIC SURVEY

### a. Planning and Organization

A request for the conduct of new anthropometric surveys of the U. S. Armed Forces was initiated by the Defense Supply Agency in April, 1964. It was planned that the Marine Corps survey would be carried out in conjunction with similar surveys of personnel in the other services of the Armed Forces.

Approval of the proposed Marine Corps anthropometric survey, with measuring to be carried out at Camp Lejeune, North Carolina and Camp Pendleton, California, was requested from the Commandant of the Marine Corps in December, 1964. Approval was granted by the Commandant of the Marine Corps in February, 1965.

Responsibility for planning and organizing the survey was assigned to the U. S. Army Natick Laboratories, Natick, Massachusetts, by the U. S. Army Materiel Command. Since the Natick Laboratories did not have either the civilian or military personnel to carry out a large-scale anthropometric survey in the field, assistance was requested from the U. S. Army General Equipment Test Activity, an element of the U. S. Army Test and Evaluation Command, located at Fort Lee, Virginia. This activity provided the military personnel, as well as the administrative and logistic support for the collection of the anthropometric data during survey. Twenty Army enlisted men were requested from Fort Meade, Maryland; these men were members of the 11th Armored Cavalry Regiment and were assigned to USAGETA, Fort Lee for temporary duty to serve on the measuring teams for the duration of the survey. This Army team carried out the Marine Corps survey, as well as similar surveys of Army and Navy personnel.

Technical direction and monitorship of the scientific aspects of the survey were the responsibilities of Natick Laboratories anthropologists. Administrative planning and supervision, scheduling and travel arrangements, and logistic support were performed by the General Equipment Test Activity under the direction of an officer who served as Project Director, assisted by a sergeant who served as Administrative Coordinator.

In the field, the survey team was directed and supervised by a Survey Officer, assisted by a noncommissioned officer in charge (NCOIC). The measuring team personnel were organized into three teams, each with a team leader and six measurers. At each installation where measuring was carried out, additional enlisted men were requested on a temporary basis to serve as data recorders.

The Project Director was authorized to establish direct coordination with the installations which would be visited by the Army measuring team. In planning the schedule for the survey, the Project Director contacted a designated project officer at each installation and provided information on the plan of operations, as well as on the number of men required to be measured, the space and equipment required, and the efficient scheduling of personnel. A liaison officer visited each installation prior to the team's scheduled arrival in order to carry out the final coordination of plans and to provide guidance to the installation project officer.

The installation project officers were designated by the respective participating installations. It was the responsibility of the installation project officer to assist the Project Director and the Survey Officer in liaison functions and installation administrative procedures, including the provision of facilities and equipment required and the scheduling of participants for a smooth flow of men through the measuring lines. He was also responsible for providing the additional personnel required, as well as the quarters and messing facilities for the measuring team personnel.

#### b. Methodology and Techniques

The first step in the technical planning for the Marine Corps survey (and the Army and Navy surveys as well) consisted of the selection of body measurements to be taken. Primary consideration was given to the problem of selecting a large enough number of measurements to be useful for a variety of requirements, while at the same time keeping the number of measurements to a manageable minimum suitable for a large-scale survey. A total of seventy body measurements was selected. These included weight, standing measurements, sitting measurements, breadth measurements, circumferences and body surface measurements, as well as measurements of the head and face, the hands, and the feet. It was felt that this selection of dimensions, while not as extensive or inclusive as it might be, still would provide most of the data and body size information required for the efficient design and sizing of military clothing and personal equipment, as well as for basic human engineering information necessary in the design of military vehicles, aircraft, and other weapons systems.

Following the selection of the body measurements to be taken, a data sheet was drawn up which would be used for the recording of the anthropometric data in the field. The format of the data sheet was arranged to facilitate transcription of the data to punch cards; column numbers for the punch cards were indicated on the data sheet. Five punch cards were required for each man measured; the first card contained the background data on each individual, while the remaining four cards contained the anthropometric data. The background data were coded to simplify punching and subsequent data processing. The body measurements were measured and recorded in millimeters, while weight was measured and recorded to the nearest whole pound. The data sheet is reproduced in the Appendix of this report. The skinfold thickness indicated for Station #7 at the end of the data sheet were not measured.

Standard techniques of measurement and standard anthropometric measuring instruments were used throughout the survey. The anthropometer (Siber Hegner 101) consists of four tubes which fit together to form a rigid rod; it is calibrated in millimeters, with the scale running from zero at the base up to 2000 mm at the top. The anthropometer has one fixed arm at the top and a second arm on a sliding sleeve which can be moved up and down on the rod. The full anthropometer was used to measure stature and other major body heights or lengths. The lower half of the anthropometer was used for lesser heights, such as crotch height, kneecap height, and calf height. The top half of the anthropometer was used as a large sliding caliper for taking body breadths and also measurements of the arms and legs, such as shoulder breadth, elbow-fingertip length, and buttock-knee length. A millimeter scale on the reverse side of the instrument was used when taking this type of measurement.

Small sliding calipers (Siber Hegner 104), with straight arms, were used for various measurements of the face and hands. Spreading calipers (Siber Hegner 106), with curved arms, were used for other measurements of the head and face. A two-meter steel tape (K & E Tip Top Wyteface), graduated in millimeters, was used for all circumference and body surface measurements.

In addition to the standard instruments, several other items of equipment were used in the survey. Foot measurements (foot length, instep length, and foot breadth) were taken with a foot board, which consists of a metal tray fitted with a sheet of millimeter graph paper covered with transparent plastic. In taking the foot measurements, a wooden block was held against the toe or the ball of the foot and the value of the dimension was read on the scale. In positioning the knees for taking leg measurements on a seated individual, a box was used as a foot-rest; squares of plywood were added to elevate the feet when necessary in order to have the thighs level and the knees at right angles.

In planning the measuring process in detail, an attempt was made to develop a system which would permit accurate and rapid measurement of men, but which also would insure a relatively smooth and efficient progression of men through the processing line. To this end, a sequence of six measuring stations was planned. The seventy body measurements to be taken were divided up into groups or blocks of measurements; each of these blocks

of measurements was taken at one of the measuring stations. The selection of the measurement groupings was based partly upon the measuring instrument (or instruments) to be used at that station and partly upon the position or posture required of the man to be measured at that station. This was done primarily to reduce time and motion to a minimum.

The actual measurement procedure may be outlined as follows. After a brief orientation concerning the purpose of the anthropometric survey, the men to be measured were requested to strip to their undershorts. Each man then reported to Station #1, where his name, rank, service number, and the rest of the background data were entered on his data sheet. He also was asked to estimate his weight and height, and then his weight was measured to the nearest pound on platform scales. The subject then moved on to Station #2 for a group of height measurements, taken with the anthropometer, and to Station #3 for a group of breadth and length measurements, taken with the large calipers. At Station #4, spreading and sliding calipers and the foot board were used for a group of head, face, hand, and foot measurements. Circumferences and body surface measurements (such as sleeve length and waist back length) were taken with a steel tape at the last two locations, Stations #5 and #6. Specific descriptions of the individual body measurements, including the position of the subject, how the measurement was taken, and the instrument used, may be found in Section 6 with the data on each measurement.

A measurer worked at each station and took the specific group of measurements assigned to that station. The measurer was assisted by a data recorder at each station.

In order to process and measure large numbers of men rapidly and efficiently, it was planned to operate three measuring lines simultaneously. Therefore, in a typical measuring operation, there were three sets of six stations, manned by three measuring teams, each of six men. With all stations in operation, 18 men were being measured at once, and normally three to five men would be waiting their turn at each station.

Before initiation of the measuring and data collection in the survey, training sessions for the Army measuring teams were held at Fort Lee, Virginia. Initially, the measuring personnel were briefed on the survey and on anthropometric techniques. Visual training aids were used to illustrate the measurements and the sequence of stations. The measurers were then shown the anthropometric instruments and assigned to their respective measuring stations. Thus, the measurers could specialize in the use of one type of instrument and learn to take a specific group or block of body measurements. Training in the use of the instruments was carried on by having the measurers practice on each other and then measure a small group of subjects in trial runs. The training and practice sessions were continued until a satisfactory level of accuracy and consistency was attained.

#### c. Locations and Dates of Measuring

Collection of anthropometric data in the Marine Corps survey was initiated in January, 1966. The Army team of measurers processed 1003 Marines at Camp Lejeune, North

Carolina between 10-14 January, 1966. The second group of 1005 Marines was measured at Camp Pendleton, California between 7-11 February, 1966. The total Marine Corps series of 2008 men was measured in ten working days; on the average, about 200 men were measured per day.

### 3. DATA PROCESSING

#### a. Data Reduction

Data processing in this survey began with the recording of the data in the field by the several recorders on special survey blanks (see Appendix). Weight was recorded in pounds and the linear measurements in millimeters.

Transfer of the anthropometric data from the survey sheets to punch-cards was accomplished daily by Marine Corps data processing elements at both Camp Lejeune and Camp Pendleton.

The punched cards were then delivered to the Anthropology Research Project. All major steps in the data processing from this point on were done by this group using the facilities of the Digital Computational Division, Aeronautical Systems Division at Wright-Patterson Air Force Base, Ohio. Computations were done on an IBM 7094-7044 direct coupled system. All programs were written in Fortran and computations were done in single precision arithmetic.

The punch-cards were read into the computer and transferred to magnetic tape. Certain minor adjustments were made to the data at this point; e.g., 10 mm was added to each crotch height value to compensate for the fact that the recorded values had been read at the lower edge of the anthropometer arm, although the measurement was actually to the top of the arm.

#### b. Editing Programs

The first step in the processing of the data tapes consisted of checking the data for errors which might have taken place at any point in the data gathering-recording-transcribing process. Two computer programs which had been developed specifically for this purpose were used.

The first of these programs, designated as XVAL (= extreme value), was used to isolate values which seemed to be inconsistent with the other data for that variable. The program performs the following functions:

1. It provides, for each variable, a list of the ten smallest and the ten largest values and the record numbers of the subjects with these values.
2. It calculates, for each variable, the mean, standard deviation, and the measures of symmetry and kurtosis ( $\beta_1$  and  $\beta_2$ ).

3. It estimates, for each variable, the values of the mean and the standard deviation on the basis of all the data with the exception of the ten largest and ten smallest values.

Data values out of line with respect to other values for the same variable were usually identified from this program's listings. Outliers were often signalled by several items in the program output. The size of the smallest or largest value itself was usually a clear indicator of a major error, as was a substantial difference between the standard deviation computed from all the data and the value estimated from the central N-20 values.

The measure of kurtosis,  $\beta_2$ , described in the section on statistical measures, was effective particularly in signalling the presence of even one or two values lying well outside the "normal" range. For a normal (i.e., gaussian) distribution, the theoretical value of  $\beta_2$  is 3.0, and the final values for this statistic were fairly close to 3 for most of the data covered by this report, being somewhat larger for variables with skewed distributions. On the other hand, the presence of a single highly extraneous value in a set of data may result in a value of  $\beta_2$  almost as large numerically as the sample size.

All values signaled by the XVAL program as questionable were investigated and obvious errors corrected. The data were then examined by use of the editing program. This program was designed to evaluate each recorded datum in terms of related data for the same individual. Each subject's stature, for example, was compared by means of multiple regression equations with other height measurements. Similarly, each subject's chest circumference measurement was weighed as reasonable or unreasonable in terms of the combination of his chest breadth and chest depth values.

Some fifty-six three-variable combinations were specified in the program for analysis. Twenty-one more-or-less typical combinations are listed in Table 1.

The primary criterion for the selection of the variables which are grouped together was that one or more members of a combination could be estimated with reasonable accuracy from the other members of the combination. Each variable was included in at least one combination, and all but a few were included in at least two.

The computer calculated regression equations for each variable in a combination in terms of the other two. Once the equations (and the associated standard errors) had been computed, the equations were used to estimate the values of the variables in each combination. These estimates were compared with the recorded values. Whenever an estimate and the recorded value differed by more than five times the appropriate standard error of estimate, an error message was printed out. This message contained, in addition to the estimate and recorded value, a considerable amount of other data about the subject in question which was deemed to be of value in evaluating the questioned datum. For example, where a stature measurement was in question, this message included the subject's other height measurements, expressed both in millimeters and in standard score form.

**Table 1. A List of Selected Editing Combinations**

<b>Stature</b>	<b>Cervicale Height</b>	<b>Shoulder Height</b>
<b>Shoulder Height</b>	<b>Waist Height</b>	<b>Crotch Height</b>
<b>Sitting Height</b>	<b>Eye Height, Sitting</b>	<b>Mid-Shoulder Height, Sitting</b>
<b>Stature</b>	<b>Crotch Height</b>	<b>Sitting Height</b>
<b>Weight</b>	<b>Neck Circumference</b>	<b>Shoulder Circumference</b>
<b>Shoulder Circumference</b>	<b>Chest Circumference</b>	<b>Waist Circumference</b>
<b>Hip Circumference</b>	<b>Upper Thigh Circumference</b>	<b>Lower Thigh Circumference</b>
<b>Lower Thigh Circumference</b>	<b>Calf Circumference</b>	<b>Ankle Circumference</b>
<b>Chest Circumference</b>	<b>Interscye Breadth</b>	<b>Interscye, Maximum</b>
<b>Chest Depth</b>	<b>Chest Breadth</b>	<b>Chest Circumference</b>
<b>Hip Breadth</b>	<b>Hip Breadth, Sitting</b>	<b>Hip Circumference</b>
<b>Shoulder Breadth</b>	<b>Maximum Forearm-Forearm Breadth</b>	<b>Shoulder Circumference</b>
<b>Biceps Circumference, Relaxed</b>	<b>Biceps Circumference, Flexed</b>	<b>Forearm Circumference, Flexed</b>
<b>Occiput-External Canthus</b>	<b>Occiput-Nasal Root</b>	<b>Occiput-Pronasale</b>
<b>Face Breadth</b>	<b>Bitragion Breadth</b>	<b>Head Breadth</b>
<b>Head Length</b>	<b>Head Breadth</b>	<b>Head Circumference</b>
<b>Hand Length</b>	<b>Palm Length</b>	<b>Thumb Crotch Length</b>
<b>Hand Breadth</b>	<b>Wrist Circumference</b>	<b>Hand Circumference</b>
<b>Crotch Height</b>	<b>Buttock-Knee Length</b>	<b>Buttock-Popliteal Length</b>
<b>Heel Breadth</b>	<b>Ball of Foot Breadth</b>	<b>Ball of Foot Circumference</b>
<b>Functional Reach</b>	<b>Sleeve Length</b>	<b>Sleeve Inseam Length</b>

Each questioned value was thoroughly examined. Errors in punching were, of course, rectified. Often, when the value recorded for one variable for a particular subject appeared to be most unlikely, other data for this subject would indicate a value for this variable which a simple observational or recording error could have turned into the recorded value. Thus, for example, a subject might have values for stature, shoulder height, waist height, and crotch height all approximately equal to the mean values of these measurements, plus a cervical height value of 1409 mm, a value about one and a half standard deviations below the mean for cervical height. In such a case, it seemed quite reasonable to believe that this man's cervical height had actually been 1490 mm — approximately average — and that the third and fourth digits had been reversed in the recording; a corresponding change was made in the data. In general, when the data indicated quite clearly both that a value was in error and what, approximately, the correct value almost certainly was, the appropriate change was made.

The large number of measurements made on each man and the generally high level of intercorrelations among the variables made it possible to estimate almost any one of the variables with high accuracy from a knowledge of the others. It was, therefore, possible to do a fairly thorough editing job on most of the variables.

### c. Computation of Statistics

Computation of the summary statistics and frequency tables were carried out on the computer, working from the magnetic tape record of the edited data. Four constants were stored in the computer for each variable before calculations began:

- (a)  $A_{i,1}$  — the lower limit of the first interval in the frequency table for the  $i$ th variable;
- (b)  $A_{i,2}$  — the maximum value attained by the  $i$ th variable;
- (c)  $A_{i,3}$  — an integer value approximately equal to the average value of the  $i$ th variable, and
- (d)  $WID_i$  — the width of the intervals for the  $i$ th variable.

The first of these constants,  $A_{i,1}$ , was, of necessity, either equal to or slightly less than the minimum value of the  $i$ th variable. Thus, the first two constants defined a range of values into which every value for the  $i$ th variable should fall. Each datum was tested as it was read into the computer to insure that it did, in fact, lie within the appropriate range.

The third of these constants,  $A_{i,3}$ , was subtracted from each value for the  $i$ th variable and all summations required for the statistical computations were based on the resulting differences. This procedure markedly reduced the size of the summations, minimizing truncation errors in these computations, and ensuring adequate results from simple precision calculations.

The first and last of the stored constants were used in establishing the frequency tables. These constants were chosen to provide tables with no more than fifty intervals.

As each data record was read into the computer:

(a) each value was checked to guarantee that it was in range. Had any non-zero value been out of range, all data for that subject would have been rejected. On the first run, no values, as should have been expected, were out of range.

(b) each non-zero value,  $x_i$ , was converted into its difference value:

$$Y = X_i - A_{i,3}$$

(c) the first four powers of Y were accumulated:

$$S_{i,1} = S_{i,1} + Y$$

$$S_{i,2} = S_{i,2} + Y^2$$

$$S_{i,3} = S_{i,3} + Y^3$$

$$S_{i,4} = S_{i,4} + Y^4$$

(d) the count of the number of non-zero values for the  $i$ th variable was accumulated:

$$N_i = N_i + 1$$

(e) the interval of the frequency table for the  $i$ th variable to which  $x_i$  belongs was determined:

$j$  = the smallest whole number less than or equal to

$$(X_i - A_{i,1})/\text{WID}_i + 1.0$$

and unity was then added to the previous count for this interval:

$$F_{i,j} = F_{i,j} + 1$$

When all of the data had been processed, the summary statistics were computed using these formulas:

$$(a) W = S_{i,1} / N_i$$

$$Z = S_{i,2} / N_i$$

$$U = S_{i,3} / N_i$$

$$V = S_{i,4} / N_i$$

followed by:

$$(b) M = \text{arithmetic mean} = W + A_{i,3}$$

$$SD = \text{standard deviation} = \sqrt{Z - W^2}$$

$$\beta_1 = \text{symmetry} = (U - 3ZW + 2W^3) / (SD)^3$$

$$\beta_2 = \text{kurtosis} = (V - 4W + 6ZW^2 - 3W^4) / (SD)^4$$

$$V = \text{coefficient of variation} = 100 \cdot SD/M$$

$$SE(M) = \text{standard error of the mean} = SD / \sqrt{N_i}$$

$$SE(SD) = \text{standard error of the standard deviation} = SE(M) \cdot 0.7071$$

The computation of the percentiles was carried out using a procedure developed by Churchill to achieve the speed and reproducibility of computer calculations while simulating the procedure of plotting cumulative frequencies on normal-probability graph paper and reading percentiles from these graphs.

The first step in these computations consisted of calculating rough values for each percentile by direct interpolation in the frequency table. To compute the  $K$ th percentile, the first interval for which the cumulative percent frequency, CPF(U), exceeded  $K\%$  was located. If  $L$  represents the lower limit of this interval; WID, the interval width; CPF(L), the cumulative percent frequency up to but not including this interval; then the  $K$ th rough percentile was computed as

$$L + WID \left( \frac{K - CPF(L)}{CPF(U) - CPF(L)} \right)$$

To illustrate this formula, we may calculate the rough 1st percentile for stature, using the data shown on page 64. We observe that the fifth interval (160.75 – 161.74 centimeters) is the first interval for which the cumulative frequency count exceeds 1%. Hence,

- L = the lower limit of this interval = 160.75  
 WID = the width of the interval = 1.0  
 CPF(L) = the cumulative percent frequency for the first four intervals = 0.70  
 CPF(U) = the cumulative percent frequency for the first five intervals = 1.29, and

the  $K$ th percentile =

$$160.75 + 1.0 \left( \frac{1.00 - 0.70}{1.29 - 0.70} \right) = 160.75 + 1.0 \cdot 0.51 =$$

$$160.75 + 0.51 = 161.26 \text{ cm.}$$

We note that the smoothed value of 161.27 cm., also given on page 65, differs from the result of these calculations by 0.1 millimeter. This computation was done for each of the 25 percentiles listed for each measured variable.

In the second step of these computations, the 25 computed percentiles were then smoothed by a process designed to simulate plotting on normal-probability graph paper and drawing a smooth line through the set of points. What is actually done is to assign an "X-value" to each raw percentile equal to the corresponding deviate of the normal distribution, fit a fourth degree polynomial to these points, and read the smoothed values from this polynomial. By using orthogonal polynomials, the computational procedure is fairly simple.

The statistics (except for  $\beta_1$ ,  $\beta_2$ , and V, which are dimensionless) were, in most instances, then multiplied by 0.1 to convert from millimeters to centimeters. The centimeter values were then multiplied by 0.3937 to provide values in inches, and weights were converted from pounds to kilograms by using 0.45359 as the multiplier.

To provide a maximum of flexibility in listing the statistics and frequency tables for photographic reproduction in this report, the results were entered on punched cards and tables prepared by listing these cards on an IBM 407 tabulator.

#### 4. THE SAMPLE OF U. S. MARINE CORPS MEN MEASURED

A total sample of 2008 Marines were processed and measured during the Marine Corps anthropometric survey. Of the total series, 1003 men were measured at Camp Lejeune, North Carolina, and 1005 men were measured at Camp Pendleton, California. In processing and analyzing the data obtained during the survey, the results were tabulated for the total series and also for the Lejeune and Pendleton subseries separately.

While the primary objective of the Marine corps anthropometric survey was to obtain body measurement data, additional information was necessary as a supplement to the anthropometric data. Therefore, two general types of background data on the men were recorded at the time they were processed and measured. In the category of military information, such items as rank, pay grade, and length of service were recorded and subsequently analyzed. An attempt also was made to record primary and present billet military occupational specialty (MOS), additional specialty or MOS, and armored vehicle crewman category or crew position, but the recording of these items was unsatisfactory and the results could not be analyzed. In the category of personal information, such items as age, birthplace, birthplace of father and mother, location of longest residence, national extraction, education, and marital status were recorded. Notations also were made on whether the individual wore glasses, his handedness, and his combat boot size. These items of background information serve to describe and characterize the sample of Marine Corps men who were measured in the survey.

a. Military Information

(1) **Military Rank and Pay Grade.** The total series of Marines measured during the 1966 anthropometric survey consisted primarily of enlisted men. Over 99 percent of the sample were enlisted men, while less than one percent were staff non-commissioned officers. No warrant officers or commissioned officers were measured during the Marine Corps survey. The distributions of rank were the same at Camp Lejeune and Camp Pendleton. On the basis of pay grade, about 85 percent of the total series of Marines were privates, privates first class, or lance corporals in the first three pay grades (E-1 to E-3). About 15 percent were in pay grades E-4 and above. The distribution of pay grades was similar in the two subseries, with slightly more than 85 percent in the first three pay grades at Camp Lejeune and slightly less than 85 percent in the first three pay grades at Camp Pendleton.

(2) **Length of Military Service.** The length of service of Marines measured in the survey ranged from two months to 12 years. The largest number of men (28 percent) had been in service for less than six months. Forty-one percent of the total series of Marines had been in service for less than one year, while 67 percent had been in service for less than two years.

b. Personal Information

(1) **Age.** The ages of the men measured in the Marine Corps survey were recorded as of their last birthday. The mean age of the total Marine Corps series was 20.88 years. The standard deviation was 2.87 years, and the coefficient of variation was 13.74 percent. The range of age for the total series was from 17 to 43 years. Approximately 66 percent of the Marines were between 18 and 20 years of age. The distribution and statistical values of age for the total Marine Corps series are given in Table 2. The Camp Lejeune subseries had a mean age of 21.01 years, with a standard deviation of 3.06 years and

Table 2. AGE OF TOTAL MARINE CORPS SERIES

---------------	------

a coefficient of variation of 14.57 percent, while the Camp Pendleton subseries had a mean age of 20.76 years, with a standard deviation of 2.66 years and a coefficient of variation of 12.81 percent. Although the mean ages of the two subseries were very similar, about 60 percent of the men at Camp Lejeune were between 18 and 20 years of age, while about 71 percent of the Camp Pendleton men were between 18 and 20 years of age. The average age for the total Marine Corps series measured, as well as for the two subseries for Camp Lejeune and Camp Pendleton may be considered to be 21 years.

(2) Birthplace and Residence. To assess the geographical distribution of the sample of men measured in the Marine Corps survey, the men were asked to give their birthplace, as well as the birthplaces of their parents. In addition, they also were asked to state the area of their longest residence prior to military service.

In the compilation of the information on geographical distribution, the individual states of the United States were grouped into the nine geographical divisions used by the Bureau of the Census. The two newest states of Alaska and Hawaii, as well as the Commonwealth of Puerto Rico and the Canal Zone, were listed separately. The large number of foreign countries which were reported were arbitrarily grouped for convenience into geographical areas.

In the total Marine Corps series, 97 percent of the men were born in the United States, a few were born in Puerto Rico or the Canal Zone, and 2.4 percent were born in foreign countries. Approximately 92 percent of the fathers were born in the United States, while about seven percent were foreign born; 94 percent of the mothers were born in the United States and about five percent were foreign born. Almost 99 percent of the Marines reported having lived in the United States prior to military service, while slightly over one percent had lived abroad.

Over 60 percent of the men in the total Marine Corps series were born in three of the nine geographical divisions, and over 62 percent had lived there; their fathers and mothers also were predominantly from these areas. The Middle Atlantic division (New York, New Jersey, and Pennsylvania) represented an area in which 24 percent of the Marines were born. The East North Central division (Ohio, Indiana, Illinois, Michigan, and Wisconsin) included 19 percent, while the South Atlantic division (Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida) accounted for 18 percent. The largest number of foreign-born in this sample were men born in Canada. In the Camp Lejeune subseries, 68 percent were born in the three eastern geographical divisions, while in the Camp Pendleton subseries, 54 percent were born in these divisions. Twelve percent of the men at Camp Pendleton were born in the Mountain or Pacific states, Alaska or Hawaii.

(3) National Extraction. During the Marine Corps survey, men were requested to give their national extraction or ethnic derivation. In the listing of national extraction, there were three categories in which the national extraction was not otherwise specified. In the three categories of American White (24.4 percent), American Negro (11.2 percent)

and American Indian (1.6 percent), the number of men comprised about 37 percent of the total Marine Corps series. Irish, German, English, Italian, French, and Polish national extractions accounted for 49 percent of the total series, while the remaining 14 percent represented some 27 other ethnic backgrounds or national extractions. A minor difference between the two subseries was that the Camp Lejeune sample included one percent of Puerto Ricans, while the Camp Pendleton group included 4.8 percent of Spanish or Mexican national extraction.

(4) Education. The educational level of the Marines was recorded on the basis of the number of years of schooling completed. In the total Marine Corps series, the range of educational level was from six years up to 17 years. About 32 percent of the total series had completed 11 years or less, while 57 percent had completed 12 years of education or the equivalent of high school. The remaining 12 percent had received schooling above high school level.

(5) Marital Status. In the total Marine Corps series, about 85 percent of the men were single and about 15 percent were married; only 0.2 percent were divorced. No individuals were recorded as being separated or widowers.

(6) Eyeglasses and Handedness. Two additional items of information were included in the background data obtained during the Marine Corps survey. Without any specific reference to contact lenses, the men were asked whether or not they wore eyeglasses. In the total Marine Corps series, 77 percent stated that they did not wear glasses, while 23 percent replied that they did wear glasses. The Lejeune and Pendleton subseries also were the same; 77 percent did not wear glasses and 23 percent did.

The Marines in the survey also were questioned as to their handedness. In the total Marine Corps series, 89 percent replied that they were right-handed, ten percent were left-handed, and one percent stated that they were ambidexterous. In the Lejeune subseries, 89 percent were right-handed, ten percent were left-handed, and one percent were ambidexterous, while in the Pendleton subseries, 88 percent were right-handed, eleven percent were left-handed, and one percent were ambidexterous.

(7) Size of Combat Boots. While the Marines were being processed prior to measurement, they were asked what size of combat boots they wore. Since many of the men did not know or could not determine the widths of their boots, the data on boot widths was incomplete or unsatisfactory; consequently, only the responses on boot size or length were tabulated. Sizes of combat boots recorded as being worn by men in the total Marine Corps series ranged from size 5 up to size 15. The modal boot size (worn by the largest number of men) for the total series was size 9, which was worn by about 30 percent of the men. Sizes 9 and 10 together were worn by 59 percent of the men. The modal size for Camp Lejeune was size 10, worn by 32.5 percent, while the modal size for Camp Pendleton was size 9, worn by 31 percent of the men. Sizes 9 and 10 together were worn by 61 percent of the men at Camp Lejeune, and by 57 percent of the men at Camp Pendleton.

In taking standard anthropometric measurements of the foot, foot length is measured from the heel to the tip of the longest toe. Information on the relative lengths of the first and second toes is of importance in the design, sizing and fit of footwear. Consequently, while the foot measurements were being taken during this survey, notations were made on the relative toe lengths. The results of these observations indicated that the first or great toe was longer than the second toe on 92 percent of the men measured, while the second toe was longer than the first on eight percent of the men.

## 5. THE STATISTICAL MEASURES

The usefulness of any anthropometric survey depends in large measure on the extent to which the mass of measurement data generated by the survey is translated by statistical analyses into summaries of value in the solution of design and related problems and which point up the important implications of the data. The statistical summaries presented in this section have been chosen in the belief that they provide the simplest and most generally useful univariate summaries of the great amount of data collected in the present survey. As valuable as these statistics may prove to be, they contain only a small portion of the useful information embodied in the survey data. Additional information is to be sought in those summaries which involve the simultaneous distribution of two or more sets of these measurement data.

The summary statistics which traditionally have been included in U. S. military anthropometric reports are provided here for each anthropometric variable. Measures of skewness and kurtosis have been added to the list of summary statistics and a frequency distribution of each variable is presented.

The means, standard deviations, standard errors, and the percentiles are listed in both metric and English or inch units. The statistics are given first (to the left of the statistics' name in the tables) in the type of units in which the data were measured and then in the converted units. The intervals in the frequency tables follow the same order.

The traditional statistics reported are as follows:

### a. The Arithmetic Mean

The arithmetic mean is the most common of the averages; it is what is usually meant when either "mean" or "average" is used without modification. The arithmetic mean of a number of values is the sum of these values divided by the number of the values. For example, since the men measured in this survey weighed a grand total of 321,281 pounds, their mean weight was:

$$x = \frac{\Sigma X}{N} = \frac{321,281}{2006} = 160.16 \text{ pounds}$$

The mean is designated in the statistical literature by several different symbols, the most common being  $x$ ,  $\mu$ , and  $M$ . When more than one set of data is being considered

at the same time, the mean values may be denoted variously as:  $x$ ,  $y$ ,  $z$ ; or  $x_1$ ,  $x_2$ ,  $x_3$ ; or  $M_x$ ,  $M_y$ ,  $M_z$ ; or  $M_1$ ,  $M_2$ ,  $M_3$ ; or  $\mu_x$ ,  $\mu_y$ ,  $\mu_z$ ; or  $\mu_1$ ,  $\mu_2$ ,  $\mu_3$ .

b. The Median

The median, a second average, designates the value of the "man-in-the middle". If all of the subjects in this survey had been lined up in order from the shortest to the tallest, the height (1744 mm) of the man in the middle of the line would be the median height. The definition of the median is identical with that of the 50th percentile, 50 percent of the data being smaller than it is and 50 percent being larger. The value of the median is to be found at the middle of the percentile tables. The procedure used in computing the percentiles and its relationship to the definition of these statistics is discussed below; that discussion is as relevant to the interpretation of the median as it is to that of the other percentile values.

The median and the arithmetic mean have approximately the same values for most of the data gathered in this survey; for these data, the question of whether one or the other is the better average is not important.

c. The Standard Deviation

The standard deviation is the basic measure of variability. If most of a set of data cluster close to their mean value, the standard deviation will be small. If on the other hand, many of the data are either much smaller or much larger than the mean, the standard deviation will be large. By definition, the standard deviation is the square root of the average (i.e., arithmetic mean) of the squared deviations from the mean value. In formula, the standard deviation equals  $SD = \sqrt{\sum (x - \bar{x})^2 / N}$ , where  $\Sigma$  is the summation operator,  $x$  represents the individual values,  $\bar{x}$  their arithmetic mean, and  $N$  the number of values.

A useful way of conceptualizing the standard deviation is to consider the middle two-thirds of a set of data such as the values of stature. The smallest value in this middle two-thirds will be about one standard deviation below the mean value and the largest value in this set will be roughly equal to the mean value plus one standard deviation. Similarly, the middle 95 percent of the data will have values ranging from approximately two standard deviations below the mean to two standard deviations above it.

The standard deviation is usually designated by  $SD$ ,  $S$ , or  $\sigma$ . Any one of these may be subscripted when several variables are being considered simultaneously. The word "sigma" ( $\sigma$ ) is sometimes used verbally to refer to the standard deviation.

d. The Coefficient of Variation

This statistic is a re-statement of the standard deviation as a percent of the mean, and it is usually denoted by the letter  $V$ . Thus,  $V = 100 SD/x$ . The relationships which were noted for the standard deviation have equivalent forms in terms of  $V$ . Thus, about

two-thirds of a set of data will lie between  $(100 - V)$  percent and  $(100 + V)$  percent of the mean, while about 95 percent will lie between  $(100 - 2V)$  percent and  $(100 + 2V)$  percent of the mean.

For many anthropometric variables, the coefficient of variation varies within a much narrower range than does the standard deviation. The value of  $V$  is often associated with the general anatomical nature of the variable involved. Long bone lengths (major heights, arm length, and so forth) tend to have coefficients of variation in the 3.5 to 5 percent range, while fleshy circumferences have coefficients which range from 6 percent to 10 percent.

#### e. The Percentiles

This group of statistics belongs to a class of measures designated as "measures of order or position". These measures can be thought of as being obtained by arranging the data in order from the smallest value up the largest one and then observing the value of the datum which lies at a specified position in the array. The smallest value, the next-to-the-largest value, the middle value, and the like are examples of this type of statistic.

Perhaps the most useful of these statistics are the percentiles. The 99 percentiles--ranging from the 1st up to the 99th-- are the values at points which separate consecutive blocks or units of one percent of the data in the ordered array. The first percentile is the value which separates the smallest one percent of the data from the 99 percent of the data with larger values, and the second percentile separates the smallest two percent from the larger 98 percent.

Twenty-five of these percentiles: the 1st, 2nd, 3rd, 97th, 98th, 99th, plus the  $h$ -th for all values of  $h$  which are multiples of 5, are listed for each anthropometric variable. Several of the listed percentiles have additional names: in particular, the 50th percentile is the median, the 25th, 50th, and 75th are the 1st, 2nd, and 3rd quartiles, and the 10th, 20th, 30th, ..., 90th are the nine deciles.

The percentiles given here are computed by a procedure which follows the spirit rather than the letter of the definition. The reasons for doing this and a description of the computational procedures are given in the section on data processing.

#### f. The Standard Errors

All statistics computed from a sample of data are subject to the effects of sampling error. When a sample has been selected by a random or other probability sampling process, it is often possible to estimate the magnitude of the sampling error. For many statistics, this estimate takes the form of the standard error of the statistic. The standard error is a standard deviation type statistic and is such that were a large number of samples of the data selected in the same way from the same population, about two-thirds of the samples would have means (or standard deviations or percentiles) with values which lie

within one standard error of the corresponding population statistic and 95 percent within two standard errors. Hence, it is conventional to suppose, when dealing with the statistics computed from a single sample, that the population statistics may well be within a standard error — up or down — of the corresponding sample statistics, and that it is rather likely that they are within two standard errors.

Each statistic has its own standard error, the value of which depends on the statistic, on the sample size, and often on the standard deviation of the data. The standard errors of the most common statistics (except the range) are, for the large samples, inversely proportional in size to the square root of the sample size.

For each variable the standard error of the mean ( $SD/\sqrt{N}$ ) and that of the standard deviation ( $SD/\sqrt{2N}$ ) are listed. The standard errors of the other statistics used in this report can be computed using the following formulas:

Statistic	Standard Error
30th through 70th Percentiles	1.3 SE of the Mean
20th, 25th, 75th, and 80th Percentiles	1.4 SE of the Mean
15th and 85th Percentiles	1.5 SE of the Mean
10th and 90th Percentiles	1.7 SE of the Mean
5th and 95th Percentiles	2.1 SE of the Mean
3rd and 97th Percentiles	2.5 SE of the Mean
2nd and 98th Percentiles	2.9 SE of the Mean
1st and 99th Percentiles	3.7 SE of the Mean
Coefficient of Variation	$V/\sqrt{2N}$
Beta I	$\sqrt{6/N}$
Beta II	$\sqrt{24/N}$

The standard error is variously designated as  $SE$ ,  $SE(\xi)$  where  $\xi$  is the statistic involved, or  $\sigma(\xi)$ . When a statistic is presented as "164.28  $\pm$  0.93", the value "0.93" is usually (though not always) the standard error of that statistic.

The standard error is a well-established statistic of widespread use, and it is generally expected that the various standard error values and a discussion of them will be included in a report of this type. Nevertheless, since probability sampling was not used in this survey, it is not clear what relationship exists between these standard errors and the actual sampling errors of the statistics reported here. A similar comment can, of course, be made about the sampling errors for all other large-scale anthropometric surveys.

The standard errors of the mean, the standard deviation, and the central percentiles are, in any event, generally rather small, most of them being less than one millimeter, a value of no real significance in evaluating these statistics.

The two statistics not often listed in military anthropometric reports are:

**g. Beta I – A Measure of Symmetry**

The statistic  $\beta_1$  is based on the fact that in a symmetric distribution every value equal to a given amount greater than the mean will be matched by a value an equal amount less than the mean, so that the cubes of the deviations from the mean – half negative and half positive – will add up to zero. Although the converse of this fact is by no means true – a zero sum of the cubed deviations in no way implies a symmetric distribution – the size of this sum when properly adjusted is often considered a useful indication of whether a set of data is unsymmetrically distributed and, if so, how badly. Such a use seems reasonably justified for the kind of data reported here.

Beta I is computed from the sum of the cubed deviations by dividing it by the sample size and the cube of the standard deviation, producing a dimensionless statistic:

$$\beta_1 = \frac{\sum(x - \bar{x})^3}{N \cdot SD^3}$$

**h. Beta II – A Measure of Kurtosis**

The statistic  $\beta_2$  is similarly computed from the fourth powers of the deviations:

$$\beta_2 = \frac{\sum(x - \bar{x})^4}{N \cdot SD^4}$$

The interpretation of  $\beta_2$  is not obvious; its major value, along with  $\beta_1$ , is that its value provides a basis for judging the level of agreement between the normal distribution and the actual distribution of the data.

The normal distribution values for  $\beta_1$  and  $\beta_2$  are 0 and 3. In theory, data distributions can deviate from either of these values without deviating from the other. For the data of this study, however, deviant values of either  $\beta_1$  or  $\beta_2$  are usually accompanied by deviant values of the other. Most of these deviant values indicate positive skewness ( $\beta_1 > 0$ ) and platykurtosis ( $\beta_2 > 3$ ).

**i. The Frequency Tables**

The frequency tables group the data for each variable into a table containing up to fifty intervals. Most of the variables, except those with the smallest ranges, were grouped into intervals 5 or 10 millimeters wide; these intervals always started with values ending in 2.5 mm or 7.5 mm to minimize the effect of any overuse of zero and five as final digits.

The tables list, for each interval, the end points of the intervals in both metric and English (inch) units; the number of men whose measurement falls within the interval

(ACTUAL FREQ): the cumulative frequency (CUMULATIVE-F), that is the number of men whose measurement did not exceed the upper end point of the interval; and these values expressed as percentages of the total number of men measured (PERCENT-FREQ and CUMUL-PCT-FQ).

## 6. THE ANTHROPOMETRIC DATA

### a. Index of Body Measurements

To facilitate ready reference to any body measurement, an index of terms is provided here. The seventy basic body measurements taken in this survey appear in the index in capital letters. Synonymous or alternate terms for body measurements also are included in the index. The listing of body measurements is cross-referenced in order to facilitate the identification of measurements under several different terms. In this way, a particular measurement may be found either by the type of measurement or by body region or area.

### b. Visual Index

In order to further assist those who may not be familiar with the terminology of body measurements, a visual index of the measurements is provided here. The visual index summarizes the seventy body measurements by means of illustrative figures showing the location of each measurement on the body. The sketches (Figures 1 to 7) are arranged to show the seven basic groupings of body measurements: Standing Measurements, Sitting Measurements, Breadth Measurements, Circumferences, Surface Measurements, Head and Face Measurements, and Hand and Foot Measurements.

### c. The Anthropometric Data

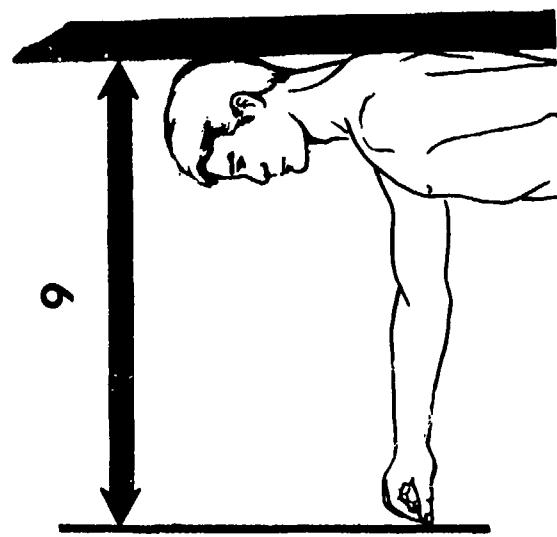

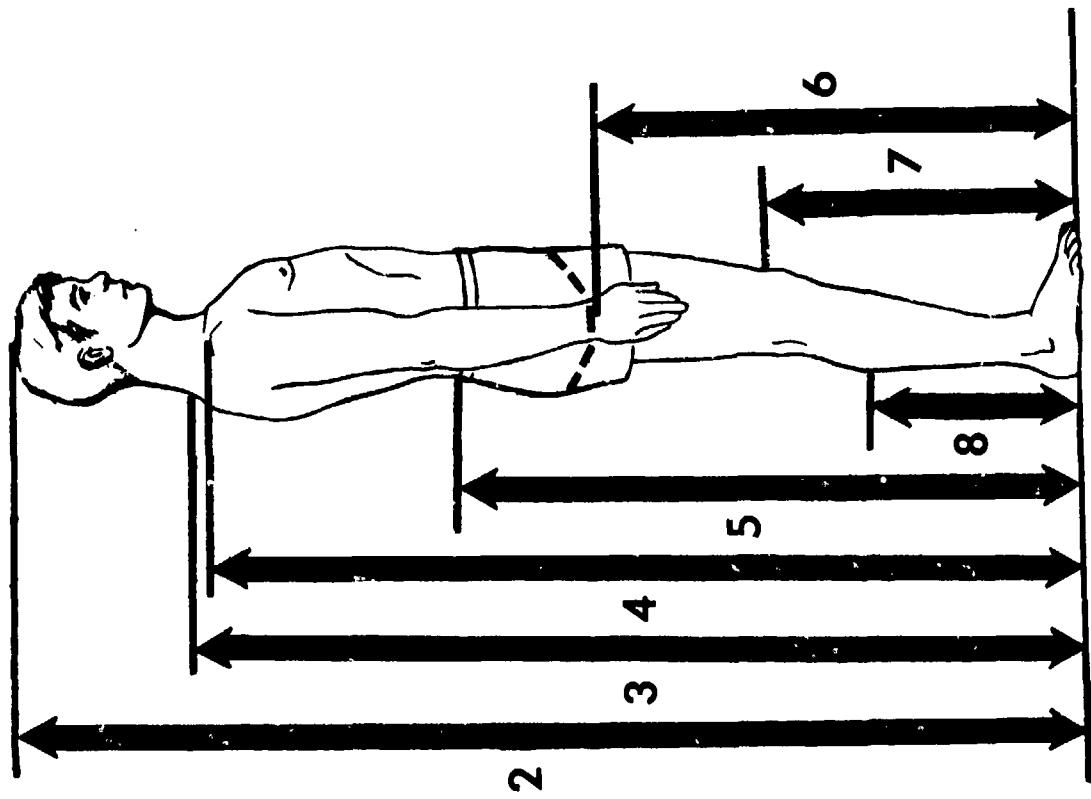

The detailed data on all of the anthropometric measurements taken during the U. S. Marine Corps survey are presented in this section. These data are based on the total Marine Corps series of 2008 men. The format adopted for the presentation of these data utilizes the direct reproduction of the computer printouts, thus obviating the possible introduction of errors in transcribing and typing the tabular material. The order of presentation of the 70 body measurements which follow is that indicated in the Visual Index.

The metric system (centimeters and millimeters) was used in the measuring. The resulting data are given in centimeters, together with the equivalent values in inches. (To convert to inches, a value in centimeters is multiplied by 0.3937; to convert to centimeters, a value in inches is multiplied by 2.54). Weight was recorded in pounds; the equivalent values in kilograms also are shown. (To convert to kilograms, a value in pounds is multiplied by 0.4536; to convert to pounds, a value in kilograms is multiplied by 2.205).

The data for each measurement are presented on two facing pages. On each right-hand page are the percentile values, from the 1st up to the 99th percentile. Below the percentiles are listed the summary statistics, consisting of the mean, the standard error of the mean ( $SE(M)$ ), the standard deviation ( $ST\ DEV$ ), the standard error of the standard deviation ( $SE(SD)$ ), the Beta I value indicating symmetry, the Beta II value indicating kurtosis, the coefficient of variation, and the sample size or number of men in the series. A sketch indicating where the measurement was taken on the body also is shown on each right-hand page, together with a description of the measurement, the position of the subject, how the measurement was taken, and the instrument used.

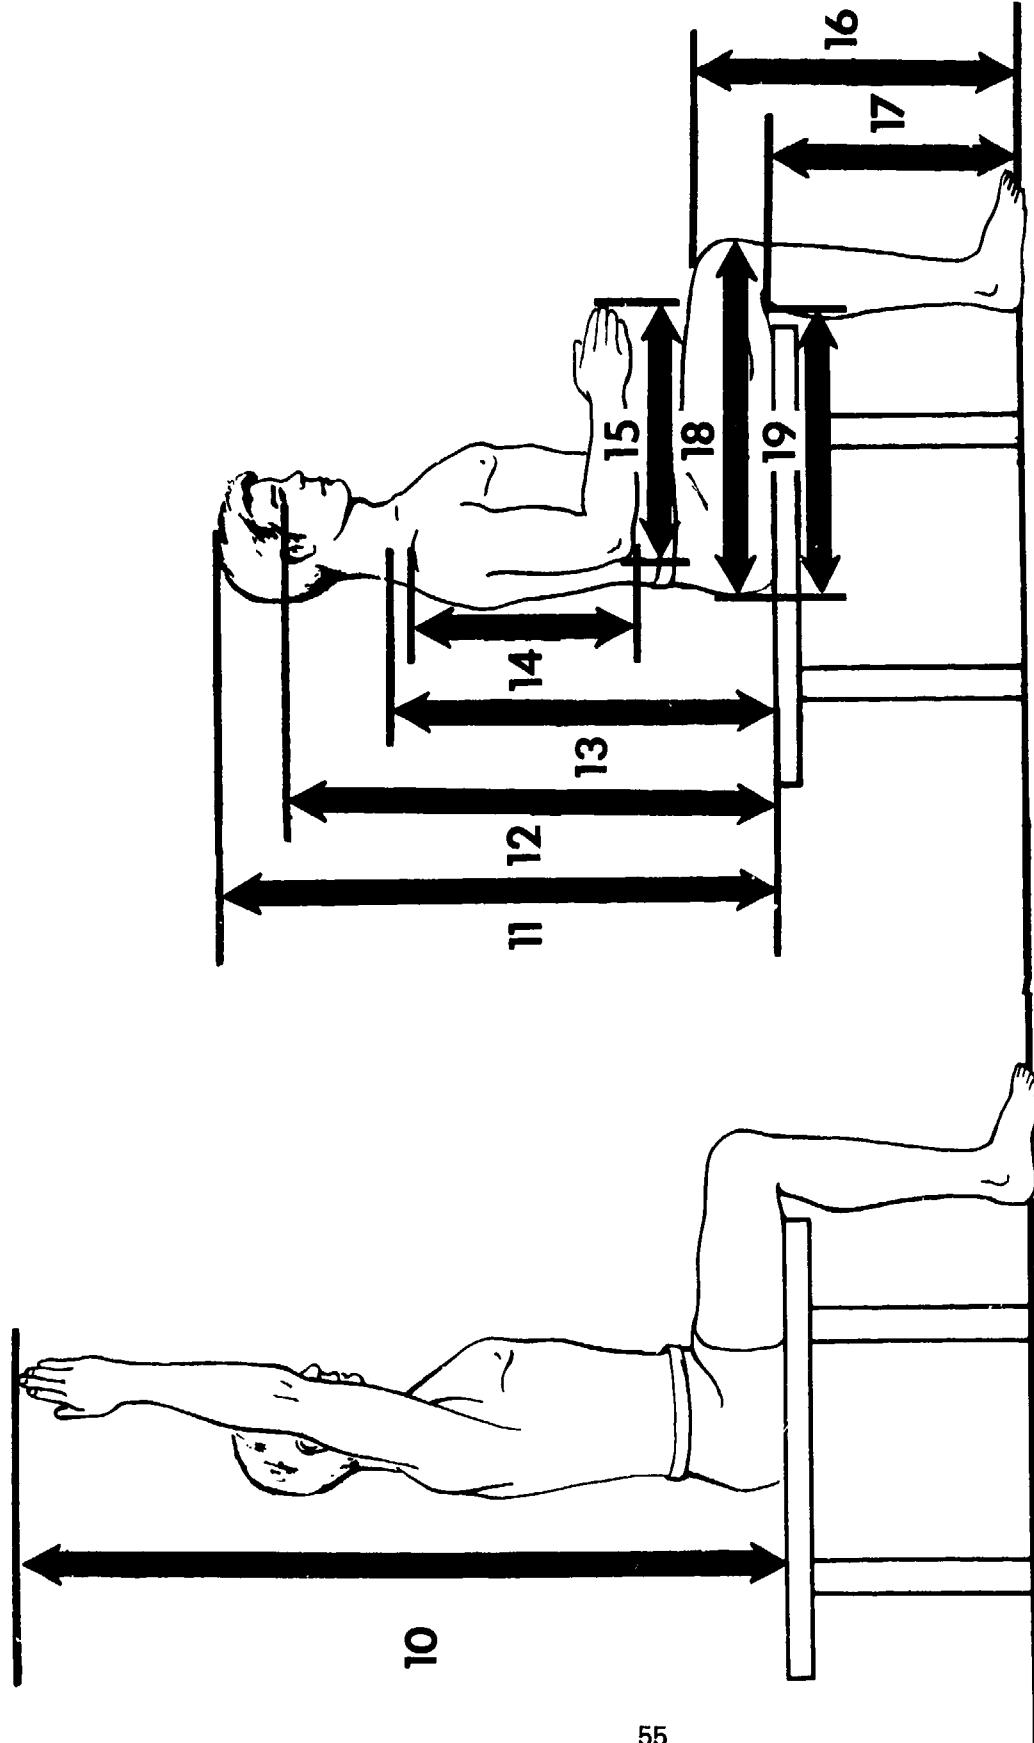

Additional data are presented on each left-handed page. The range of variation for each measurement (from the smallest value up to the largest value) is divided into intervals; these intervals are shown on the left of the page in both centimeters and inches. The frequencies (or distribution) of the men measured are shown on the right, opposite the respective intervals. The first column of frequencies (ACTUAL FREQ) gives the actual frequencies or numbers of men whose measurements fell within the indicated intervals. For example, in the case of stature (page 64), 130 men (of the total series of 2008)

had statures of between 68.80 and 69.18 inches (or 174.75 and 175.74 centimeters). The second column (CUMULATIVE-F) indicates the cumulative frequencies of the men in the series. Thus, 1174 men in this series had statures of 69.18 inches (175.74 centimeters) or less. The third column (PERCENT-FREQ) represents the actual frequencies expressed as percentages of the total series; in other words, 6.47 percent of the 2008 men measured had statures of between 68.80 and 69.18 inches (or 174.75 and 175.74 centimeters). The fourth column (CUMUL-PCT-FQ) shows the cumulative frequencies expressed as percentages; thus, 58.47 percent of the men in this series were 69.18 inches (175.74 centimeters) or less in stature.

**Waist Height (Iliocristale Height):**  
Subject stands erect, with heels together. Waist height is measured as the vertical distance from the floor to the upper edge (iliac crest) of the right hip bone. An anthropometer is used.

**Crotch Height:** Subject stands erect, with his feet initially apart and then brought together after the anthropometer is in place. Crotch height is measured as the vertical distance from the floor (or standing surface) to the crotch. An anthropometer is used, with the anthropometer arm firmly in contact with the highest point in the crotch.

## 9 Functional Reach

**Functional Reach:** Subject stands erect against a wall, with his right arm extended forward horizontally, and with the tips of his thumb and index finger pressed together; his shoulders must remain in contact with the wall. Functional reach is measured as the horizontal distance from the wall to the tip of the thumb. An anthropometer is used.

**Sitting Height:** Subject sits erect, with head level, and with his feet resting on a surface adjusted so that his knees are bent at right angles. Sitting height is measured as the vertical distance from the sitting surface to the top of the head (vertex). An anthropometer is used, with the anthropometer arm firmly touching the scalp to compress the hair.

## 12 Eye Height, Sitting

**Eye Height, Sitting:** Subject sits erect, with head level, and with his feet resting on a surface adjusted so that his knees are bent at right angles. Eye height is measured as the vertical distance from the sitting surface to the inner corner (internal canthus) of the right eye. An anthropometer is used.

**Mid-Shoulder Height, Sitting:** Subject sits erect, with head level, and with his hands resting on his thighs. Mid-shoulder height is measured as the vertical distance from the sitting surface to the top of the right shoulder, midway between the neck and the outer point (acromion) of the shoulder. An anthropometer is used.

**Elbow-Fingertip Length (Forearm-Hand Length):** Subject sits erect, with his arms bent to form right angles at the elbows and with his hands extended. Elbow-fingertip length is measured as the horizontal distance from the back of the right elbow to the tip of the middle finger of the extended right hand. An anthropometer is used.

**Buttock-Knee Length:** Subject sits erect, with his feet resting on a surface adjusted so that his knees are bent at right angles. Buttock-knee length is measured as the horizontal distance from the back of the right buttock to the front of the right knee. An anthropometer is used.

**Shoulder Breadth (Bideltoid Breadth):**  
 Subject sits erect, with his arms bent to form right angles at the elbows and with his elbows held against the body. The maximum breadth across the shoulders is measured at the level of the bulges of the deltoid muscles in the upper arms. An anthropometer is used, and is held horizontally.

**Upper Thigh Circumference:** Subject stands erect, with his feet slightly apart. The horizontal circumference of the right upper thigh is measured. A steel tape is used, with the tape passing just below the gluteal furrow.

SYMMETRY--BETA I = 0.32  
KURTOSIS--BETA II = 3.32  
COEFFICIENT OF VARIATION = 7.48

SAMPLE SIZE = 2008

**Arm Scye Circumference:** Subject stands erect, with his right arm initially raised and then lowered after the tape is in place. The vertical circumference of the scye (sleeve armhole area) is measured. A steel tape is used, with the tape passing under the right armpit and over the outer point (acromion) of the right shoulder.

**Biceps Circumference, Relaxed:**  
Subject stands erect, with his right arm held slightly away from the body. The circumference of the right upper arm is measured at the level of the biceps muscle, midway between the shoulder and the elbow. A steel tape is used.

**38 Biceps Circumference, Flexed**

Biceps Circumference, Flexed:

Subject stands erect, with his right arm bent, fist clenched, and biceps muscle flexed. The maximum circumference of the right upper arm is measured at the greatest bulge of the flexed biceps muscle. A steel tape is used.

78.04	30.73

**Sleeve Length:** Subject stands erect, with his arms bent at the elbows, fists pressed together in front of him, and with his arms held horizontally. Sleeve length is measured as the horizontal distance along the outer surface of the right arm, from the middle of the back, over the elbow, to the center of the bony prominence at the outer edge of the wrist (styloid process of the ulna). A steel tape is used.

## THE SUMMARY STATISTICS

• • •

**Occiput-External Canthus:** Subject sits erect, with head level. The distance from the back of the head (occiput) to the outer corner (external canthus) of the right eye is measured. An anthropometer is used.

## THE SUMMARY STATISTICS

\*\*\*\*

**Occiput-Tragion:** Subject sits erect, with head level. The distance from the back of the head (occiput) to the cartilaginous notch (tragion) at the front of the right ear is measured. An anthropometer is used.

### THE SUMMARY STATISTICS

\*\*\*

**Face Breadth (Bzygomatic Breadth):**  
 Subject sits erect, with head level.  
 The maximum horizontal breadth of  
 the face is measured between the  
 lateral projections of the cheek bones  
 (zygomatic arches). Spreading  
 calipers are used

### THE SUMMARY STATISTICS

• • •

**Interpupillary Breadth:** Subject sits erect, with head level. The distance between the centers of the pupils of the eyes is measured. Sliding calipers are used.

#### THE SUMMARY STATISTICS

\*\*\*

**Thumb Crotch Length:** Subject sits, with his right hand and fingers extended, palm up, and with his thumb extended away from the hand. The length of the thumb crotch is measured from the skinfold at the base of the thumb to the notch between the first and second fingers. Sliding calipers are used.

**Instep Length:** Subject stands erect, with his right foot in a foot measuring box, and with his weight evenly distributed on both feet. The length of the instep of the right foot is measured from the back of the heel to the center of the inner ball of the foot (first metatarsal-phalangal joint). A foot measuring box is used.

**Ball Of Foot Circumference:** Subject stands erect, with his feet slightly apart and with his weight evenly distributed on both feet. The circumference of the right foot is measured. A steel tape is used, with the tape passing over the inner and outer balls of the foot (first and fifth metatarsal-phalangeal joints).

22.97	1 ST	9.04

**Instep Circumference:** Subject stands erect, with his feet slightly apart, and with his weight evenly distributed on both feet. The vertical circumference of the instep of the right foot is measured. A steel tape is used, with the tape passing under the foot and over the junction of the leg and foot.

## 7. SUMMARY TABLES OF ANTHROPOMETRIC DATA

The detailed data for the seventy body measurements taken on the total Marine Corps series are presented in the previous section. However, to facilitate ready reference to values for groups of similar or related body measurements, the anthropometric data are summarized here in a series of four tables. These tables show the anthropometric data for the total Marine Corps series. The data in these tables are presented as statistical values, as well as percentile values.

The order of presentation of the seventy body measurements in these tables is that indicated in the Visual Index (page 54), with the measurements grouped under the following headings: Weight, Standing Measurements, Sitting Measurements, Breadth Measurements, Circumferences, Surface Measurements, Head and Face Measurements, Hand Measurements and Foot Measurements.

In the summary tables, the data are given in both centimeters and inches. Exceptions are weight, which is given in kilograms in the metric tables and in pounds in the inch tables, and age, which is given in years.

### a. Tables of Statistical Values

The first set of tables (Table 3 in centimeters and Table 4 in inches) contains the statistical values for the seventy anthropometric measurements. These are: the number of men (N), the mean, the standard error of the mean (SE(M)), the standard deviation (S.D.), the standard error of the standard deviation (SE(SD)), the coefficient of variation (V(%)), the range, and the stature ratio for each measurement.

The range is indicated by the minimum value (Min.), the maximum value (Max.), and the total range, or the difference between the minimum and maximum values. The range or spread of each body measurement (from the lowest value on the smallest man to the highest value on the largest man) has been tabulated into intervals, as indicated in the data pages, Section 6, c. (page 52).

The stature ratio is the result of dividing the mean value of each measurement by the mean value of stature. This ratio is a useful indication of proportion. The ratios shown in the tables may be converted into percentages by multiplying by 100. Thus, the stature ratio of sitting height is 0.521, indicating that mean sitting height for the total Marine Corps series is 52.1 percent of mean stature.

Table 3. STATISTICAL VALUES FOR TOTAL MARINE CORPS SERIES

No.	Measurements	N	Mean	SE(X)	S.D.	Values in Centimeters			Range	Max.	Total	Stature ratio

**b. Tables of Percentile Values**

The second set of tables (Table 5 in centimeters and Table 6 in inches) shows selected percentile values for all of the seventy anthropometric measurements, from the 1st up to the 99th percentile. In addition, the range or spread from the 1st to the 99th percentile is indicated for each measurement. The range is obtained by subtracting the 1st percentile value from the 99th percentile value. In these tables, the median is indicated by the 50th percentile value.

### c. Tables of Design Limits

Anthropometric data may be presented or summarized in various ways; these data also may be utilized or applied in a variety of methods. A listing of statistical values for body measurements (Tables 3 and 4), such as means and standard deviations, is conventional, but data in this form are not very useful for design purposes. Minimum and maximum values for a measurement indicate the range of variation for that measurement, but seldom are attempts made to accommodate these extremes in design and sizing.

The use of percentile values (Tables 5 and 6) is more realistic in the design and sizing of clothing and equipment, since the various percentile values indicate limits of the measurement for particular segments of the population sample. Thus, the 5th and 95th percentile values, for example, indicate the limits of a measurement for 90 percent of the population, since the smallest five percent and the largest five percent are, by definition, left out of consideration.

The use of percentile values is practical, as well as convenient. However, the statistical concept of percentile values for anthropometric data may be confusing or not readily understandable for some who require these data for design purposes. Percentile values, in a different way, may be thought of as design limits for various specified segments of the population under consideration — in fact, it is not even necessary to refer to percentile values in this interpretation.

Accordingly, tables of design limits may be prepared, derived from the percentile values for anthropometric measurements. Tables 7 (in centimeters) and 8 (in inches) are tables of design limits based upon U. S. Marine Corps data. In these tables, the columns headed 100, 98, 95, 90, 80, and 50 percent indicate the segments of the sample which would be expected to be accommodated or fitted by using the two values shown for the anthropometric measurements. In the case of stature, for example, 50 percent of the Marines are between 67.0 and 70.4 inches tall, 95 percent are between 64.1 and 73.8 inches tall, while the total sample (100 percent) is between 61.7 and 77.4 inches tall. A sizing system utilizing chest circumferences of between 32.4 and 43.4 inches would accommodate 98 percent of Marines, whereas design limits of 35.5 and 38.5 inches in chest circumference would fit only 50 percent of the Marine population.

It is obvious that as the spread or range between two values for a dimension is reduced, the percentage of the population that can be fitted or accommodated will be decreased. The values in these tables indicating 100 percent coverage are the minimum and maximum values for any dimension. The 98 percent coverage is based upon the 1st and 99th percentile values, the 95 percent coverage is based upon the 2½ and 97½ percentile values, and the 90 percent coverage is based upon the 5th and 95th percentile values. The 50 percent coverage, of course, is based upon the 25th and 75th percentile values, indicating the middle half of the population.

The use of so-called design limits, based upon percentile values, is an even more practical and flexible method for applying anthropometric data in the solution of design and sizing problems. The design limits actually represent guide lines or parameters for initial design and sizing. Conversely, these design limits also may be used in another way, in that they may be utilized to estimate the degree of coverage or accommodation for items of clothing or equipment which have been designed, produced, and are already in use. The design limits therefore may also be of assistance when considering redesign or resizing in order to improve fit, accommodation, and logistic efficiency.

Table 7. U. S. MARINE CORPS DESIGN LIMITS

## Values in Centimeters

No.	Measurements	100 percent	percent	95 percent	20 percent	80 percent	50 percent

## 8. ANALYSES AND DISCUSSION OF THE ANTHROPOMETRIC DATA

### a. Standards for Height and Weight

Physical standards for height and weight of the U. S. Marine Corps may be found in Marine Corps Order 6100.3G, dated 23 September 1975. The following standards are specified for men, regardless of age:

Height (inches)	Weight (pounds)	
	minimum	maximum
78	153	235
77	151	230
76	147	225
75	143	219
74	139	214
73	135	209
72	131	203
71	127	197
70	123	192
69	119	186
68	115	181
67	111	175
66	107	170
65	106	165
64	105	160

Comparable physical standards for height in the U. S. Army range from a minimum of 60 inches up to a maximum of 80 inches. Minimum acceptable weights for the Army, regardless of age, are the same as those for the Marine Corps. Maximum acceptable weights for the Army, however, are graded by age groups, and considerably exceed those for the Marine Corps.

With reference to the anthropometric data for height and weight, mean height for the present series of Marines was 68.72 inches, and the range of height was from a minimum of 61.7 inches up to a maximum of 77.5 inches. Mean weight was 160.16 pounds, and the range of weight was from a minimum of 109.5 pounds up to a maximum of 247.5 pounds. There were 40 men (2 percent) whose height was below the minimum standard of 64 inches, but no men exceeded the maximum standard of 78 inches in height. There were no men who were below the minimum standard weight for their heights, but 171 men (8.5 percent) were above the maximum standard weight for their heights and could be considered to be overweight by Marine Corps standards.

### b. Estimated and Measured Weight and Stature

Occasionally a comment is made to the effect that accurate measurements of height and weight really are not necessary and that since most men know their height and weight, these may be ascertained merely by asking the individual. During a physical or medical examination, a physician frequently will only ask the subject for his height and weight. The Marine Corps anthropometric survey afforded an opportunity to compare weight and height as estimated by Marines with actual measurements of their weight and height.

As a part of the background information obtained during the survey, each man was asked to give his weight (in pounds) and his height (in inches). Following these estimates by the individual, each man was weighed and his stature was measured.

The detailed data on estimated weight and stature for the total Marine Corps series are shown in Tables 9 and 10, respectively. The format for these tables is similar to that for the data on measured weight and stature given in Section 6 (pages 62 - 65). Statistical values for estimated and measured weight and stature for the total Marine Corps series, as well as for the Camp Lejeune and Camp Pendleton subseries, are shown in Table 11. The corresponding percentile values for estimated and measured weight and stature are given in Table 12.

In all cases, the values for both estimated weight and stature are consistently higher than the values for measured weight and stature. In the total Marine Corps series, mean estimated weight was 3.72 pounds higher than mean measured weight. In the series from Camp Lejeune, the difference between mean estimated weight and mean measured weight was 3.66 pounds, while in the Camp Pendleton series, this difference was 3.77 pounds. By comparison, the U. S. Army survey of 1966 showed a mean estimated weight 2.28 pounds higher than mean measured weight.

In the total Marine Corps series, mean estimated stature was 1.44 inches higher than mean measured stature. In the Camp Lejeune series, mean estimated stature was 1.47 inches higher than mean measured stature, while this difference was 1.39 inches in the Camp Pendleton series. In the U. S. Army survey of 1966, mean estimated stature was 1.10 inches higher than mean measured stature.

The percentile values for estimated weight and stature, as compared with the percentile values for measured weight and stature (Table 12), show the same consistently higher values for the estimated measurements.

It may be suggested that differences between estimated and measured weight and stature may be greater in small, short men and in heavy, tall men. This may be attributable to the supposition that both small, short men and heavy, tall men are somewhat more sensitive about their general body size. Perhaps small men may tend to overestimate or exaggerate their size, while large men may tend to underestimate or minimize their body size. The anthropometric data in their present form do not warrant firm conclusions

on this subject; this should be investigated using the present data in the form of individually paired comparisons of estimated and measured weight and stature.

c. Comparisons of U. S. Marine Corps Subseries

The total of 2008 Marine Corps men measured in this survey consisted of two subseries: 1003 men were measured at Camp Lejeune, North Carolina and 1005 men were measured at Camp Pendleton, California. As might be expected, the two groups were very similar in body size, and also in age.

The Camp Lejeune subseries was slightly older, with a mean age of 21.01 years, as contrasted with a mean age of 20.76 years for the Camp Pendleton subseries. Mean weights for the two groups were 159.95 pounds for the Camp Lejeune subseries and 160.38 pounds for the Camp Pendleton subseries. Mean statures for the two groups were virtually identical: 68.72 and 68.73 inches, respectively. Mean chest circumferences for the two groups also were practically identical: 37.08 and 37.14 inches, respectively. The anthropometric data indicated, therefore, that for all practical purposes the two subseries of Marines measured at Camp Lejeune and Camp Pendleton were identical in body size.

d. U. S. Marine Corps Data of 1949

An anthropometric survey of U. S. Marine Corps men was carried out in 1949 by William J. Beer, a Marine Corps officer. In this survey, 1000 men were measured at Camp Lejeune, North Carolina, and 1000 men were measured at Camp Pendleton, California. The purpose of the survey was to obtain and analyze body size information on the Marine Corps population for application and utilization in the design and sizing of Marine Corps clothing and equipment. Although the anthropometric data from this survey were never published in an official report, they were used extensively in the development and sizing of Marine Corps clothing and individual equipment. This work was carried on for some years at the Marine Corps Depot of Supplies, Philadelphia, Pennsylvania, by Beer and by Emil M. Misura, also a Marine Corps officer.

It may be of interest here to compare the two series of Marines measured in 1949 and in 1966. Anthropometric data, in the form of mean values for 15 body measurements taken in both surveys, are shown in Table 13. Mean age for the 1966 series was about three-quarters of a year higher than that of the 1949 series. The 1966 series was four pounds heavier and about 0.4 inches taller than the 1949 series. In all measurements but one (head circumference), mean values were greater for the 1966 series of Marines than for the 1949 series. In particular, the circumferences or body girths were markedly higher for the 1966 series — a reflection of the increase of four pounds in weight.

e. U. S. Marine Corps Data of 1973

A significant study of the body size and body composition of U. S. Marine Corps men was carried out by Howell F. Wright (Marine Corps Development and Education

Command, Quantico, Va.) and Jack H. Wilmore (Department of Physical Education, University of California, Davis, Calif.); their report was published in *Aerospace Medicine* in March, 1974.<sup>22</sup>

The study was conducted at Quantico, Virginia, utilizing subjects drawn from the various Quantico school and base populations. A random sample of 297 Marines between 18 and 53 years of age was used to determine a simple, but accurate, clinical and field test for estimating body composition from several anthropometric measurements. A total of 9 skinfold, 15 circumference, and 9 diameter measurements, in addition to age, height and weight, were assessed at least twice, and were then used in a stepwise, linear, multiple regression analysis to determine the most accurate equations to estimate relative body fat and lean body weight. The latter were determined by hydrostatic weighing. Relative body fat could be predicted from five anthropometric measurements with an  $R = 0.87$ , and a standard error of estimate of 3.08 percentage units. Lean body weight could be predicted from three anthropometric measurements with an  $R = 0.90$  and a standard error of estimate of 2.16 kg. Additional analyses of the data were conducted with the subjects divided into three categories. Age was found to have little or no relationship to any one of the body composition factors.

On the basis of this study, it was concluded that the traditional method of estimating one's best weight through standard height-weight tables is a crude and unacceptable way to ascertain the individual's actual body composition. A distinction between one's lean body weight, fat weight, and total body weight, is what is actually desired. This can be accomplished through a rather simple assessment of several anthropometric measurements, which are then placed in a regression equation to estimate the approximate body composition parameters.

This study demonstrated that, by taking two measurements — weight and abdominal circumference — an accurate ( $R = 0.88$ ) estimation of one's body composition can be performed. Regression equations involving three to five anthropometric measurements are given for use in a clinical situation where instrumentation and time do not present problems as in field situations.  $R$  coefficients of 0.86 to 0.90 were found to exist between various anthropometric measurements and the components of body composition. In addition, this study found these predictions to be independent of age.

While this study involved less than 300 Marines and was carried out several years after the Marine Corps anthropometric survey of 1966, it is of interest to compare the anthropometric data from the two sources. Statistical values for the anthropometric measurements, as well as for the skinfold thickness measurements and the body composition measures of this study are shown in Table 14 (in centimeters) and in Table 15 (in inches); percentile values for these data were not reported.

The Marines in this study were considerably older, with a mean age of 28.73 years, as compared to a mean age of 20.88 years for the 1966 Marine Corps series. Mean weight for the men in this study was 171.81 pounds, while the 1966 series showed a mean weight of 160.16 pounds, a difference of 11.65 pounds. The men of this study were over one inch taller, with a mean stature of 69.74 inches, while the 1966 series had a mean stature of 68.72 inches. Chest and waist circumferences also were larger for the men of this study. Mean chest circumference for the study series was 38.46 inches, compared with a mean chest circumference of 37.11 inches for the 1966 Marines, while mean waist circumference was 32.95 inches for the study series, and 31.22 inches for the 1966 series. The Quantico Marines utilized in this study of body composition thus were older, heavier, taller, and larger in body size than the Marines measured in the 1966 anthropometric survey.

#### f. Comparison of U. S. Army and U. S. Marine Corps Data

In a technical report of the results of the U. S. Army anthropometric survey of men in 1966 (see Reference 12, page 13), comparisons of data from all of the U. S. Armed Forces were made on the basis of seven selected body measurements: weight; stature; sitting height; shoulder breadth; hip breadth, sitting; chest circumference and waist circumference. The anthropometric data from the present Marine Corps survey were included in these comparative tables.

In the area of clothing and individual equipment, the U. S. Army and the U. S. Marine Corps have somewhat comparable requirements; in fact a great deal of U. S. Army combat clothing and equipment is utilized by the Marine Corps. In view of this area of mutual interest, a detailed comparison of the anthropometric data from the Army and from the Marine Corps is pertinent here.

Statistical values for the seventy body dimensions measured on both Army and Marine Corps personnel in 1966 are given in Table 16 (in centimeters) and in Table 17 (in inches). The statistical values are: the number of men (N), the mean, the standard error of the mean (SE(M)), the standard deviation (S.D.), the standard error of the standard deviation (SE(SD)), the coefficient of variation (V(%)), the range, and the stature ratio. The range is indicated by the minimum value (Min.), the maximum value (Max.), and the total range, or the difference between the minimum and maximum values. Percentile values for the Army and Marine Corps series are given in Table 18 (in centimeters) and in Table 19 (in inches). The percentiles consist of selected values from the 1st up to the 99th percentile, together with the range from the 1st to the 99th percentile.

The U. S. Army series of 1966 had a mean age of 22.17 years, while the U. S. Marine Corps series had a mean age of 20.88 years, giving a difference of 1.29 years. Despite this slight difference in age, both series essentially represent groups of young men. In mean weight, the Marines were 1.06 pounds heavier; mean weight for the Marines was 160.16 pounds, while the Army series had a mean weight of 159.10 pounds. The two series were virtually identical in mean stature: 68.71 inches for the Army and 68.72

inches for the Marines. Mean chest circumference for the Marines was 37.11 inches and mean chest circumference for the Army series was 36.92 inches, a difference of less than 0.2 inches.

As indicated in the tables of comparative data, the body measurements of Army and Marine Corps personnel were very closely similar, and in some instances, actually were identical. In general, the Marine Corps data showed lower standard deviations and a lesser range of variation between minimum and maximum values; this may be attributable to the difference in sample size between the two series. Percentile values for the two series also are closely similar, with the Marine Corps series showing a lesser range between 1st and 99th percentile values.

On the basis of the anthropometric data, it may be concluded that for all practical purposes, these samples of U. S. Army and U. S. Marine Corps men are virtually identical in body size and proportions.

## 9. SUMMARY AND CONCLUSIONS

An anthropometric survey of U. S. Marine Corps men was carried out in January and February, 1966. During the survey, seventy body measurements were made on a total sample of 2008 Marines; 1003 men were measured at Camp Lejeune, North Carolina and 1005 men were measured at Camp Pendleton, California. The resulting anthropometric data are presented in detail and discussed in this report.

The U. S. Marine Corps anthropometric data are compared with U. S. Army anthropometric data, and it was found that Marine Corps personnel are very similar to U. S. Army personnel in body size and proportions.

The U. S. Armed Forces anthropometric surveys of 1966, of which the Marine Corps survey was a part, represented the first major updating of anthropometric data on the U. S. military population in some twenty years. These surveys also provided, for the first time, standard anthropometric data for all of the U. S. Armed Forces.

Body size information, in the form of anthropometric data, is required as a basis for design criteria in the development of military equipment and materiel. Information on the range of variability in body size and proportions within the military population is necessary for the design, sizing, and tariffing of military clothing and individual equipment. Anthropometric data provided a basic input for the design and human engineering of military equipment and materiel. The Marine Corps anthropometric data should be of wide use and application in the design, sizing, and human engineering of clothing, personal equipment, and other materiel intended for use by the United States Marine Corps.

## APPENDIX - The Data Sheet (front)

## U. S. MARINE CORPS ANTHROPOMETRIC SURVEY - 1966

ANTHROPOMETRIC MEASUREMENTS

<u>Location</u>	<u>Subject No.</u>	<u>Card 1:</u>	<u>Card 2:</u>
<u>Unit</u>	<u>Date</u>	<u>Station #1 - Scales</u>	
<u>Age</u>		1 WEIGHT (to nearest pound)	7
<u>Rank</u>	<u>Enlisted<sup>1</sup>, Staff NCO<sup>2</sup>, Warrant Off.<sup>3</sup>, Comm.Off.<sup>4</sup></u>	<u>Station #2 - Standing on floor; full anthropometer</u>	
<u>Pay Grade</u>	1, 2, 3, 4, 5, 6, 7, 8, 9	2 STATURE	10
<u>Service No.</u>		3 CERVICAL HEIGHT	14
<u>Primary MOS</u>		4 SHOULDER HEIGHT (ACROMIALE)	18
<u>Present Billet MOS</u>	13	5 WAIST HEIGHT (ILIOCRISTALE)	22
<u>Additional Specialty or MOS</u>	17	6 FUNCTIONAL REACH (from wall)	26
<u>Armored Vehicle Crewman</u>	21	<u>SL. HGT on box; half anthropometer</u>	
<u>Length of Service: years completed</u>	24	7 CROTCH HEIGHT	30
months, up to 12	26	8 PATELLA HEIGHT, TOP	34
<u>Age: years, at last birthday</u>	28	9 CALF HEIGHT	37
<u>Birthplace, Subject</u>	30	<u>Sitting, with foot box; half anthropometer</u>	
<u>Birthplace, Father</u>	32	10 ARM REACH, UPWARD	40
<u>Birthplace, Mother</u>	34	11 SITTING HEIGHT	44
<u>Longest Residence</u>	36	12 EYE HEIGHT, SITTING	48
<u>National Extraction</u>	38	13 MID-SHOULDER HEIGHT, SITTING	51
<u>Education: years of schooling completed</u>	42	14 KNEE HEIGHT, SITTING	54
<u>Marital Status: single<sup>1</sup>, married<sup>2</sup>, septd.<sup>3</sup>, divorced<sup>4</sup>, widower</u>		15 POPLITEAL HEIGHT, SITTING	57
<u>Nude Weight (nearest pound)</u>	45	<u>Station #3 - Standing; large calipers.</u>	
<u>Height, without shoes (nearest inch)</u>	48	16 CHEST DEPTH	50
<u>Glasses: not worn 1, worn 2</u>	50	17 CHEST BREADTH, SKIN	63
<u>Handedness: right-handed<sup>1</sup>, left-handed<sup>2</sup>, ambidextrous<sup>3</sup></u>	51	18 HIP BREADTH, STANDING	66
<u>Combat Boots (size and width worn)</u>	52	<u>Sitting; large calipers</u>	
		19 OCCIPUT - EXTERNAL CANTHUS	69
		20 OCCIPUT - TRAGION	72
		21 HEAD HEIGHT (VERTEX-TRAGION)	?
		22 SHOULDER-ELBOW LENGTH	10

**APPENDIX - The Data Sheet (back)**

23 FOREARM-HAND LENGTH	13	47 SHOULDER CIRCUMFERENCE	16
24 BUTTOCK-KNEE LENGTH	16	48 CHEST CIRCUMFERENCE	20
25 BUTTOCK-POPLITEAL LENGTH	19	49 WAIST CIRCUMFERENCE	24
26 SHOULDER BREADTH (BIDEXTROID)	22	50 HIP (BUTTOCK) CIRCUMFERENCE	28
27 MAXIMUM FOREARM-FOREARM BREADTH	25	51 ARM SCYE CIRCUMFERENCE	32
28 HIP BREADTH, SITTING	28	52 BICEPS CIRCUMFERENCE, EXTENDED	35
<u>Station #4 - Sitting; spreading calipers</u>		53 WRIST CIRCUMFERENCE	38
29 FACE BREADTH (BIZTONOMATIC)	31	54 HAND CIRCUMFERENCE (METACARPALS)	41
30 BITRAGION DIAMETER	34	55 BICEPS CIRCUMFERENCE, FLEXED	44
31 HEAD LENGTH	37	56 FOREARM CIRCUMFERENCE, FLEXED	47
32 OCCHIPUT - NASAL ROOT	40	<u>Station #6 - Standing on floor; tape</u>	
33 OCCHIPUT - PRONASALE	43	57 MAIST BACK LENGTH	50
34 HEAD BREADTH	46	58 SHOULDER LENGTH	53
<u>Sitting; sliding calipers</u>		59 INTERSCYE DISTANCE	56
35 INTERPUPILLARY DISTANCE	49	60 INTERSCYE MAXIMUM	59
36 PACE LENGTH (MERTON-NASAL ROOT)	51	61 SLEEVE LENGTH	62
37 HAND LENGTH	54	62 SLEEVE INSTEAM	65
38 PALM LENGTH	57	63 VERTICAL TRUNK CIRCUMFERENCE	68
39 THUMB CROTCH - 1ST FINGER BASE	60	<u>Standing on box; tape</u>	
40 HAND BREADTH (METACARPALS)	62	64 UPPER THIGH CIRCUMFERENCE	72
<u>Standing on box; sliding calipers</u>		65 LOWER THIGH CIRCUMFERENCE	Card 5: 7
41 HEEL BREADTH	65	66 CALF CIRCUMFERENCE	10
<u>Standing; foot board</u>		67 ANKLE CIRCUMFERENCE	13
Toe Length: 1st toe longer <sup>1</sup> , 2nd toe longer <sup>2</sup>		68 HEEL-ANKLE CIRCUMFERENCE	16
42 FOOT LENGTH	69	69 INSTEP CIRCUMFERENCE	19
43 BALL OF FOOT LENGTH (INSTEP)	72	70 BALL OF FOOT CIRCUMFERENCE	22
44 BALL OF FOOT BREADTH	7	<u>Station #7 - Skinfold calipers</u>	
<u>Station #5 - Standing; tape</u>		71 DORSAL HAND	25
45 HEAD CIRCUMFERENCE	10	72 JUXTA-NIPPLE	27
46 NECK CIRCUMFERENCE	13	73 TRICEPS	29
		74 SUB-SCAPULAR	31
		75 M-A-L XIPHOID	33
		76 SUPRA-ILIAC	35
